Dear Dr Smiley

Re: Mr James SAINT - [REDACTED]

Diagnosis: Left sided sigmoid diverticulosis but without any significant inflammatory change – biopsies normal
Single colonic polyp removed
One or two aphthous ulcers in the terminal ileum of doubtful significance – probably physiological
Currently under investigation by neurologists for potential transverse myelitis

I saw James following his colonoscopy. He does have a moderate amount of sigmoid diverticulosis at a relatively young age. However, there are no signs of any complications from the diverticulosis and biopsies taken from this area did not show any inflammation. He does have quite a lot of muscular hypertrophy in this segment of the colon associated with the diverticulosis, and indeed they did note that on the ultrasound scan so there is no doubt that the sigmoid colon in the left side of his abdomen is more powerful and perhaps more prone to going into spasm which might explain the pains on the left side of his tummy and the more frequent bowel action. There is nothing particularly to do about this.

He doesn't require any surveillance colonoscopy as he only had one polyp removed.

I have not made any definite further arrangements to follow him up in clinic but happy to see him at any point as need be.

Kind regards
Yours sincerely

Dictated, but sent unsigned to avoid delay
